Lecture 14

Early Inflation

A possible solution for:

Why a hot Big Bang?
Horizon problem
Flatness problem
Monopole problem
Origin of primordial structure
Early inflation, Hot Big Bang, Decelerating Expansion, Late inflation by “Dark Energy”
Early Inflation: the first $10^{-33}$ seconds

tiny fraction of a second

DAWN OF TIME

inflation

380,000 years

13.7 billion years
1980: Inflation (Alan Guth)

- Universe born from “nothing”?
- A quantum fluctuation produces a tiny bubble of “False Vacuum”.
- High vacuum energy drives exponential expansion, also known as “inflation.”
- Universe expands by huge factor in tiny fraction of second, as false vacuum returns to true vacuum.
- Expansion so fast that virtual particle-antiparticle pairs get separated to become real particles and antiparticles.
- Stretches out all structures, giving a flat geometry and uniform T and ρ, with tiny ripples.
- Inflation launches the Hot Big Bang!
Planck Units

Planck Length: de Broglie wavelength $\sim$ Schwarzschild radius

$$ E = M c^2 = \frac{hc}{\lambda} \quad \Rightarrow \quad \lambda = \frac{h}{M c} \quad R_s = \frac{2GM}{c^2} $$

$$ (\lambda R_s)^{1/2} \sim L_p \equiv \left(\frac{hG}{c^3}\right)^{1/2} \sim 10^{-35} \text{ m} $$

Planck Time

$$ t_p \equiv \frac{L_p}{c} = \left(\frac{hG}{c^5}\right)^{1/2} \sim 10^{-43} \text{ s} $$

Planck Mass

$$ M_p = \frac{L_p c^2}{G} = \frac{h}{L_p c} = \left(\frac{hc}{G}\right)^{1/2} \sim 10^{25} m_p \sim 10^{19} \text{ GeV/c}^2 $$

Planck Energy

$$ E_p \equiv M_p c^2 = \left(\frac{hc^5}{G}\right)^{1/2} \sim 10^{19} \text{ GeV} $$

Limits of Quantum Mechanics and General Relativity. Need Quantum Gravity theory (as yet unknown) to describe physics at these scales.
Quantum Vacuum

Heisenberg Uncertainty principle:

\[ \Delta E \Delta t \sim \hbar \]

Can violate energy conservation:
“Borrow” energy from the vacuum, but only for a short time.
To create a particle-antiparticle pair, need \( \Delta E > 2 m c^2 \).
These “virtual” pairs live only briefly, \( \Delta t \sim h / \Delta E \).

Vacuum is not empty. Filled with all types of virtual pairs.
Quantum Vacuum

Like waves on the sea.

Quantum fields oscillate in many possible wave modes

$$\phi(x,t) \quad \psi_i(x,t) \quad A(x,t), \quad \ldots$$

Each wave mode is a Harmonic Oscillator,

Potential energy:

$$V(\phi, \psi_i, A, \ldots) = m_\phi |\phi|^2 + m_\psi |\psi|^2 + \ldots$$

Ladder of discrete Energy States:

$$E(n) = \left(n + \frac{1}{2}\right)\hbar\omega$$

Zero-point energy:

$$E(0) = \frac{1}{2}\hbar\omega = \frac{hc}{2\lambda}$$

Quantum vacuum = all wave modes in ground state.
### Vacuum Energy Density

#### Waves in a Box:

- For mode $n$, the wavelength $L = n \lambda$
- Wave number $k \equiv \frac{2\pi}{\lambda} = \frac{2\pi n}{L}$
- Mode width $\Delta k = \frac{2\pi}{L}$

#### Density of states in 6-D phase space:

$$dn = \frac{g}{L_x L_y L_z \Delta k_x \Delta k_y \Delta k_z} = \frac{g}{(2\pi)^3}$$

- Photons have $g = 2$ polarisations.
- Electrons have $g = 2$ spin states.

Each mode is a simple harmonic oscillator.

#### Zero-point energy per mode:

$$\langle E(k) \rangle = \frac{1}{2} \left( \frac{\hbar c}{\lambda} \right) = \frac{\hbar c k}{2}$$

Short waves dominate.
Cosmological Constant Problem

Range of wavelengths in the Cosmological box:

\[ \lambda > L_p \sim \left(\frac{\hbar G}{c^3}\right)^{1/2} \sim 10^{-35} \text{ m} \quad k_{\text{max}} \sim \frac{2\pi}{L_p} \]

\[ \lambda < \frac{c}{H_0} \sim 4300 \text{ Mpc} \sim 10^{26} \text{ m} \quad k_{\text{min}} \sim \frac{2\pi}{c / H_0} \]

\[ \varepsilon_{\text{vac}} = \frac{g \hbar c}{2\pi^2} \left( k_{\text{max}}^4 - k_{\text{min}}^4 \right) \approx \frac{g \hbar c}{16\pi^2} \left( \frac{2\pi}{L_p} \right)^4 = \frac{\pi^2 g \hbar c}{L_p^4} \sim \frac{E_P}{L_p^3} \]

\[ \Omega_{\text{vac}} = \frac{\rho_{\text{vac}}}{\rho_{\text{crit}}} \sim \left( \frac{\pi^2 g \hbar}{c L_p^4} \right) \left( \frac{8\pi G}{3 H_0^2} \right) \sim \frac{8\pi^3 g}{3} \left( \frac{c / H_0}{L_p} \right)^2 \sim 10^{120} \]

Cosmological Constant problem:

Observe \( \Omega_\Lambda \sim 0.7 \) \quad Predict \( \Omega_\Lambda \sim 10^{120} \)

Why is \( \Omega_\Lambda \) so small, yet not exactly zero?

Why does quantum vacuum energy not gravitate?
Flatness Problem

Why was the initial geometry flat?

If exactly flat, then always so.

To be roughly flat today, \( \Omega_0 = 1 + \varepsilon \)

must initially be incredibly close to flat:

\[
\Omega(x) = \frac{8\pi G \rho}{3H^2} = \frac{\Omega_R x^4 + \Omega_M x^3 + \Omega_\Lambda}{\Omega_R x^4 + \Omega_M x^3 + \Omega_\Lambda + (1 - \Omega_0) x^2}
\]

\[
\Omega(x \to \infty) - 1 \Rightarrow \frac{\varepsilon}{\Omega_R x^2} \sim 10^{-119} \left( \frac{\varepsilon}{0.01} \right) \left( \frac{10^{-5}}{\Omega_R} \right) \left( \frac{10^{61}}{x} \right)^2
\]

\[
\Omega_R \sim 10^{-5} \quad x \sim \frac{c/H_0}{L_P} \sim 10^{61}
\]

**Flatness problem:** Why was \( \Omega \) initially so close to 1?

How did the Universe know precisely how fast to expand?
**Horizon Problem**

Why is the universe almost perfectly isotropic?

Distant regions were never in causal contact.

Yet we see:

- Same CMB temperature to 1 part in $10^5$.
- Similar galaxy distributions.
The Hubble Deep Fields

Thousands of galaxies, just a few stars.

Similar galaxy distributions, supporting the Cosmological Principle.

HDF North

HDF South
$T = 2.73 \text{ K}$

$dT / T \sim 10^{-5}$

2003 WMAP all-sky

Dipole and foreground galaxy removed

Snapshot at $z=1100$ of quantum fluctuations stretched by inflation.
Dark matter potential wells that seed later galaxy formation.
**The Horizon: How far can we see?**

Suppose \( R(t) = R_0 \left(\frac{t}{t_0}\right)^\alpha \)

\[
\chi_H = \eta_0 = \int_{t_1}^{t_0} \frac{c \, dt}{R(t)} = \frac{c}{R_0} \int_{t_1}^{t_0} \frac{t^\alpha}{t^\alpha} \, dt = \left(\frac{c}{R_0}\right) \times \left\{ \begin{array}{lcl}
1 - \left(\frac{t_1}{t_0}\right)^{1-\alpha} & \text{if} & \alpha < 1 \\
1 - \alpha & \ln\left(\frac{t_0}{t_1}\right) & \text{if} & \alpha = 1 \\
\left(\frac{t_0}{t_1}\right)^{\alpha-1} - 1 & \frac{\alpha - 1}{\alpha - 1} & \text{if} & \alpha > 1 
\end{array} \right.
\]

As \( t_1 \to 0 \),

*Finite for \( \alpha < 1 \),

*Infinite for \( \alpha =1, >1 \).

\[
\begin{align*}
\text{matter - dominated} : \quad & \alpha = 2/3 \\
\text{radiation - dominated} : \quad & \alpha = 1/2
\end{align*}
\]
Particle Horizon at $z = 1100$

$$L_H(t_R) = \frac{R(t_R)c}{R(t)} dt = \frac{c}{(1+z)} \int_{1+z}^{\infty} \frac{dx}{H(x)} \approx \frac{c}{(1+z)H_0} \int_{1+z}^{\infty} \frac{dx}{\sqrt{x^4 \Omega_R + x^3 \Omega_M}}$$

$$= \frac{2c}{(1+z)H_0 \sqrt{\Omega_M} x_0} \left( \sqrt{1 + \frac{x_0}{1 + z}} - 1 \right)$$

$$= \frac{c}{H_0} \frac{2 \left( \sqrt{4.6} - 1 \right)}{1100 \sqrt{0.3 \times 3500}} = 3.4 \times 10^{-5} \frac{c}{H_0} \approx 190 \left( \frac{0.7}{h} \right) \left( \frac{0.3}{\Omega_M} \right)^{1/2} \text{ kpc}$$

Expands by factor $1 + z = 1100$ to $\sim 200 \text{ Mpc}$ today.

How did these 20,000 causally disconnected regions know what temperature to be, to 1 part in $10^5$?
Magnetic Monopole Problem

The GUT (Grand Unified Theory) phase transition should produce "topological defects" that look like magnetic monopoles.

We don’t see any.

Why is the universe devoid of magnetic monopoles?

Phase Transitions among Forces

Quantum Gravity

\[ E_P \sim 10^{19} \text{GeV} \]

GUT

\[ E_{GUT} \sim 10^{15} \text{GeV} \]

electro-weak

\[ E_{EW} \sim 250 \text{GeV} \]

strong

weak

electromagnetic

gravity

Today:

\[ kT \sim 10^{-3.6} \text{eV} \]
Inflation launches the Big Bang

\[ R = e^{Ht} \]

expand by factor \( f = e^{Ht} \) in time \( t = \frac{\ln f}{H} \)

\[ H \sim \left( \frac{8\pi G \rho_{\text{vac}}}{3} \right)^{1/2} \]

What came before \( t = 0 \) ?

Early inflation replaces the Big Bang singularity.

Launches the Hot Big Bang.

Horizon problem: Expands a causally-connected region.
Flatness problem: Flattens the geometry.
Monopole problem: Moves primordial monopoles beyond horizon.
Seeding structures: Stretches out small quantum fluctuations.
During inflation:

Particle horizon expands

\[ R \propto e^{H t} \]

\[ L_H(t_2) = \int_{t_1}^{t_2} \frac{R(t_2)c}{R(t)} dt = \frac{c}{H} e^{H(t_2-t_1)} \]

Dramatic cooling

\[ x \equiv 1 + z \propto \frac{1}{R} \propto e^{-H t} \]

\[ T = T_0(1 + z) \propto \frac{1}{R} \propto e^{-H t} \]

Geometry flattens

\[ \Omega(x) = \frac{8\pi G \rho}{3H^2} = \frac{\Omega_R x^4 + \Omega_M x^3 + \Omega_\Lambda}{\Omega_R x^4 + \Omega_M x^3 + \Omega_\Lambda + (1-\Omega_0) x^2} \]

\[ \Rightarrow \frac{\Omega_\Lambda}{\Omega_\Lambda + (1-\Omega_0) x^2} \approx 1 - \frac{(1-\Omega_0)}{\Omega_\Lambda} x^2 \]
How much inflation needed?

Present horizon: $R_H \sim c / H_0 \sim 4300 \text{ Mpc} \sim 10^{26} \text{ m}$

Planck time: $t_p \sim 10^{-43} \text{ s}$ horizon $\sim c t_p \sim L_p \sim 10^{-35} \text{ m}$

Post-inflation redshift: $z_p \sim \frac{E_p}{kT_{CMB}} \sim \frac{10^{19} \text{ GeV}}{10^{-3.6} \text{ eV}} \sim 10^{32}$

$L_p \Rightarrow L_p f z_p \sim f \times 10^{-3} \text{ m}$ Need inflation factor $f \sim 10^{29} \sim e^{67}$

GUT phase transition: $E_{GUT} \sim 10^{15} \text{ GeV}$ $E \sim kT \sim R^{-1} \sim t^{-1/2}$

$t_{GUT} \sim \left( \frac{E_p}{E_{GUT}} \right)^2 t_p \sim 10^8 t_p \sim 10^{-35} \text{ s}$ horizon $\sim c t_{GUT} \sim 10^8 L_p \sim 10^{-27} \text{ m}$

Redshift $\sim z_{GUT} \sim \frac{E_{GUT}}{kT_{CMB}} \sim \frac{10^{15} \text{ GeV}}{10^{-3.6} \text{ eV}} \sim 10^{28}$

$L_{GUT} \Rightarrow L_{GUT} f z_{GUT} \sim f \times 10^9 \text{ m}$

Inflation factor $f \sim 10^{17} \sim e^{40}$

Time $t \sim \ln(f) / H$

$\sim 40 t_{GUT} \sim 10^{-33} \text{ s}$
Requirements for Inflation:

Friedmann momentum equation:

\[ \frac{\ddot{R}}{R} = - \frac{4\pi G}{3c^2} (\varepsilon + 3p) \]

\[ = - H_0^2 \sum_w \Omega_w x^{3(1+w)} \frac{1 + 3w}{2} \]

Acceleration requires a sufficiently negative pressure:

\[ p < - \varepsilon / 3 \]

\[ w < -1 / 3 \]

*Inflation* requires the *dominant* component to have \( w < -1 / 3 \).

“Dark Energy” is driving inflation now:

\[ w_\Lambda = -1 \quad p_\Lambda = -\varepsilon_\Lambda \]

\[ \frac{\ddot{R}}{R} \Rightarrow + \frac{8\pi G}{3c^2} \varepsilon_\Lambda = H_0^2 \Omega_\Lambda \]

\[ \Rightarrow R \propto \exp(H_\Lambda t) \quad H_\Lambda \equiv H_0 \sqrt{\Omega_\Lambda} = \frac{\Lambda}{3} \]

But today’s Dark Energy is negligible at early times.
What causes Early Inflation? An evolving Scalar Field?

Klein-Gordon equation

\[ E^2 = p^2 c^2 + m^2 c^4 \]

\[ E \rightarrow i \hbar \frac{\partial}{\partial t} \quad p \rightarrow -i \hbar \nabla \]

\[ \ddot{\phi} - c^2 \nabla^2 \phi = \frac{m^2 c^4}{\hbar^2} \phi = \frac{m^2 \phi}{\left( M_P t_P \right)^2} \]

For a spatially-uniform field:

\[ \nabla \phi \approx 0 \quad \ddot{\phi} = -\frac{dV}{d\phi} \]

massive field:

\[ V = \frac{m^2 \phi^2}{2 \left( M_P t_P \right)^2} \]

Higgs field:

\[ V \propto -a \phi^2 + b \phi^4 \]

Vacuum energy starts large, declines to 0 at late times.
Scalar Field Dynamics

During inflation:

Just after inflation:

Today:

Kinetic energy of the oscillations is damped. Re-heats the Universe, creating all types of particle-antiparticle pairs, launching the Hot Big Bang.
Spontaneous Symmetry Breaking

Why start in the false vacuum, not near $V \sim 0$?

Before GUT phase transition:

After GUT phase transition:

Tunnel to true vacuum? No.

Latent heat released, converts to particle-antiparticle pairs, re-heating the universe.

Small excess ($10^{-9}$) of particles.
Scalar Field Equation of State

**Equation of State:** \( w = \frac{p}{\varepsilon} \)

\[
p_{\phi} = \frac{1}{2} \frac{1}{\hbar c^3} \left( \dot{\phi}^2 + c^2 \nabla \phi^2 \right) - V(\phi)
\]

\[
\varepsilon_{\phi} = \frac{1}{2} \frac{1}{\hbar c^3} \left( \dot{\phi}^2 + c^2 \nabla \phi^2 \right) + V(\phi)
\]

**Uniform field:** \( c^2 (\nabla \phi)^2 \ll \dot{\phi}^2 \)

( Inflation makes spatial gradients small. )

**Required for inflation:**

\[
w = \frac{p}{\varepsilon} = \frac{\dot{\phi}^2}{\dot{\phi}^2 + 2 \hbar c^3 V} < -\frac{1}{3}
\]

\[
\varepsilon + 3p = 2 \left( \frac{\dot{\phi}^2}{\hbar c^3} - V \right) < 0
\]

\[
\frac{\dot{\phi}^2}{\hbar c^3 V} < 1
\]

The potential energy must dominate the kinetic energy.
Scalar Field Dynamics

**Equation of State:** \( w = p / \epsilon \)

\[
p_\phi = \frac{\dot{\phi}^2}{2 \hbar c^3} - V(\phi)
\]

\[
\epsilon_\phi = \frac{\dot{\phi}^2}{2 \hbar c^3} + V(\phi)
\]

**Evolution of energy density:**

\[\epsilon \propto x^{3(1+w)} \quad dt = -dx / (x H)\]

\[
\dot{\epsilon} = \frac{d\epsilon}{dx} \frac{dx}{dt} = \left(3(1+w)\frac{\epsilon}{x}\right)(-x H) = -3H(\epsilon + p)
\]

**Evolution of uniform scalar field:**

\[
\dot{\epsilon} = \frac{\dot{\phi}^2}{\hbar c^3} + \frac{\partial V}{\partial \phi} \dot{\phi} = -3H(\epsilon + p) = -3H \frac{\dot{\phi}^2}{\hbar c^3}
\]

\[
\ddot{\phi} + 3H \dot{\phi} = -\hbar c^3 \frac{\partial V}{\partial \phi}
\]
Scalar Field Dynamics

Hubble Drag:
Acceleration damped by expansion:

$$\ddot{\phi} + 3H \dot{\phi} - c^2 \nabla^2 \phi = -\hbar c^3 \frac{\partial V}{\partial \phi}$$

( Inflation makes spatial gradients small. )

"Slow-Roll" Approximation:

$$3H \dot{\phi} = -\hbar c^3 \frac{\partial V}{\partial \phi}$$

Terminal velocity:

$$\dot{\phi} \Rightarrow -\frac{\hbar c^3}{3H} \frac{\partial V}{\partial \phi}$$

"Like a snowflake falling"

Friedmann equation:

$$H^2 \approx \frac{8\pi G}{3} \frac{\epsilon}{c^2} \approx \frac{8\pi G}{3} \frac{V}{c^2}$$

Required for Inflation:

$$\frac{\dot{\phi}^2}{\hbar c^3 V} \Rightarrow \frac{\hbar c^3}{9H^2V} \left( \frac{\partial V}{\partial \phi} \right)^2$$

$$= \frac{\hbar c^5}{24\pi G} \left( \frac{\partial V / \partial \phi}{V} \right)^2 \ll 1$$

Inflation requires a "very flat" potential.
Long slow roll across the “plateau” (potential dominated) gives $> 60$ e-foldings of inflation (cooling, flattening).

Latent heat released during (kinetic energy dominated) rapid roll and damped oscillations at the end fills the universe with photons and particle-antiparticle pairs, launching the Hot Big Bang.

Initial quantum vacuum fluctuations mean different regions finish at slightly different times, giving the small ($10^{-5}$) temperature/density ripples we see on the CMB.
A Multi-verse? Chaotic Inflation?

Vacuum with quantum fluctuations.

Many bubbles of false vacuum inflate, with:
Different physical constants.
Different spatial dimensions.

**ANTHROPIC PRINCIPLE:**

Most bubbles quickly re-collapse or expand too fast to form stars or are otherwise unsuitable as habitats for Life.

Is our visible universe part of a big bubble lasting long enough, and with suitable physical laws, to allow beings like us to evolve?
